XC9213 Series

Synchronous Step-Down DC/DC Controller IC - Input Voltage : 25V

■ GENERAL DESCRIPTION
The XC9213 series is N-ch & N-ch drive, synchronous, step-down DC/DC controller IC with a built-in bootstrap driver circuit. Output will be stable no matter which load capacitors, including low ESR capacitors, are used. Resistance (RSENSE) of about several 10mΩ will be required as a current sense. The phase compensation is also run when a low ESR capacitor is used. In addition, the circuit is double protected by the ways of limiting the current while detecting overshoot current and making output shutdown at any given timing by a protection time setting capacitor (CPRO). The output voltage can be set freely within a range of 1.5V~15.0V with 1.0V (accuracy±2%) of internal reference voltage by using externally connected resistors (RFB1, 2). Synchronous rectification PWM control can be switched to non-synchronous current limit PFM/PWM automatic switchable control (=voltage between RSENSE pins) by using the MODE pin. The series has a built-in voltage detector for monitoring a selected voltage by external resistors. During stand-by (CE pin = low) all circuits are shutdown to reduce current consumption to as low as 4.0μA or less.

■ APPLICATIONS
● E-book Readers / Electronic dictionaries
● Smart phones / Mobile phones
● Note PCs / Tablet PCs
● Digital audio equipments
● Multi-function power supplies

■ FEATURES
Input Voltage Range : 4.0V ~ 25.0V
Output Voltage Range : 1.5V ~ 15.0V externally set
Reference voltage : 1.0V (±2%)
Oscillation Frequency : 300kHz (±15%)
Output Current : 5A (VIN=5.0V, VOUT=3.3V)
Control : PWM/PFM manual control
Current Limit Protection : Sense Voltage=170mV
High Efficiency : 93% (VIN=5.0V, VOUT=3.3V, IOUT=1A)
Detect Voltage Function : Detects 0.9V/Open-drain output
Stand-by Current : ISTB = 4.0μA (MAX.)
Load Capacitor : Low ESR capacitor
Shutdown Time : Adjustable by CPRO pin
Built-in Bootstrap : External Nch-Nch Drivers
Package : TSSOP-16
Environmentally friendly : EU RoHS Compliant, Pb Free

(*) CE, MODE pin voltage

1) 1.4V ≤ High Level ≤ 6V
   - The CE pin and the MODE pin can be connected directly to the high level power supply.

2) 6V < High Level ≤ 30V
   - The CE pin and the MODE pin should be connected to over 1kΩ resistor when connecting

Circuit 23

Circuit 24

Circuit 25
< Error Amplifier >
The error amplifier is designed to monitor output voltage. The amplifier compares the reference voltage with the feedback voltage. When a voltage lower than the reference voltage is fed back, the output voltage of the error amplifier increases.

< Ramp Wave Generator >
The Ramp Wave Generator is organized by the circuits generates a saw-tooth waveform based on the oscillator circuit which sets an oscillation frequency and a signal from the oscillator circuit.

< PWM Comparator >
The PWM Comparator compares outputs from the error amp. and saw-tooth waveform. When the voltage from the error amp's output voltage is low, the external switch will be set to OFF.

< U.V.L.O. Comparator >
When the VIN pin voltage is lower than 1.5V (TYP.), the circuit sets EXT/2 to "L" and the external transistor is forced OFF.

< Voltage Regulator >
The voltage regulator block generates 4.0V voltage for the bootstrap circuit. The regulator block is also the power supply for the internal circuit. Please do not use the regulator block as a local power supply.

< Vref with Soft Start >
The reference voltage, Vref (FB pin voltage)=0.9V, is adjusted and fixed by laser trimming. The soft-start circuit protects against inrush current, when the power is switched on, and also to protect against voltage overshoot. It should be noted, however, that this circuit does not protect the load capacitor (CL) from inrush current. With the Vref voltage limited and depending upon the input to the error amps, the operation maintains a balance between the two inputs of the error amps and controls the EXT1 pin's ON time so that it doesn't increase more than is necessary.

< CE Control Logic >
This function controls the operation and shutdown of the IC. When the voltage of the CE pin is 0.4V or less, the mode will be chip disable, the channel's operations will stop. The EXT1/2 pins will be kept at a low level (the external N-ch MOSFET will be OFF). When the CE pin is in a state of chip disable, current consumption will be no more than 4.0 μA. When the CE pin's voltage is 1.4V or more, the mode will be chip enable and operations will recommence. With soft-start, 95% of the set output voltage will be reached within 8mS (CSS: 4700pF (TYP.)) from the moment of chip enable.

< Voltage Detector >
The voltage detector of the XC9213 series is FB type. The reference voltage is 0.9V (TYP.) and the detect voltage can be set by external resistors. The output is N-ch Open Drain type. The detector is switched on/off with DC/DC by the CE pin.
OPERATIONAL EXPLANATION (Continued)

Protection Circuit Operation (Current Limit, Latch Protection Circuit, and Short Protection Circuit)

Shown above is a timing chart for protection circuit operations. When the output current changes from normal to an overcurrent condition, the current-limiting circuit detects the overcurrent condition as a voltage drop occurring, by virtue of the current-sensing resistor, at the VSENSE pin. Upon detection, the current-limiting circuit limits the peak current passed through the high-side N-ch MOSFET at every clock pulse (state ①). It is possible to regulate the value of limited current by varying the resistance value of the current-sensing resistor. A protection circuit (protective latch circuit), which is designed to stop the clock, functions if the overcurrent condition continues for a predetermined time (state ②). Time delay before the protective latch circuit functions is adjustable by the capacitance connected to the CPRO pin (typically 4.7 ms if CPRO has 4,700 pF). The protective latch circuit is reset by turning off and on, or by a disable action followed by an enable action using the CE pin.

If, furthermore, the output is short-circuited (state ③) and VOUT decreases to a value close to 0 V, the short-circuit protection circuit detects the condition by means of the FB pin and stops the clock with no time delay. The short-circuit protection circuit is reset by turning off and on or by a disable action followed by an enable action using the CE pin, as with the protective latch circuit.

< Mode Control Logic >

A timing chart for automatic switching of current-limiting PFM/PWM is shown above. High-level of the MODE pin allows PWM operations to occur for synchronous rectification (state ①). When the MODE pin shifts to low-level, current-limiting PFM/PWM automatic switching occurs with synchronous rectification stopped. Consequently, the low-side N-ch MOSFET is constantly off under this condition. In addition, a comparison is made for the purposes of automatic switching, between the ON time of the high-side N-ch MOSFET determined by the internal error amp. and the time required for the current passed at every clock pulse through the high-side N-ch MOSFET to reach a preset amount of current. The longer one is selected and becomes on duty (state ② or ③). If the time determined by the error amp. is longer than the other, PWM operation occurs. Current-limiting PFM operation occurs if the time taken by the current passing at every clock pulse to reach a preset amount of current is longer. Thus the automatic switching mechanism achieves high efficiency under light to heavy load conditions.
**TYPICAL APPLICATION CIRCUIT**

*Please place $C_{\text{IN}}$ close to $R_{\text{SENSE}}$ as much as possible, so that an impedance does not occur between the elements.  
*Please place $C_{\text{IN}}, R_{\text{SENSE}}, T_{\text{r1}}, T_{\text{r2}}, L$, $C_{\text{L}}$, and $SD_{1}$ as close as possible to each other.

**EXTERNAL COMPONENTS**  
* Please refer to the DC/DC simulation section of the Torex web site (http//:www.torex.co.jp) for more details.

- **Recommended N-ch MOSFETs for $T_{\text{r1}}$ and $T_{\text{r2}}**
  - **I_{\text{OUT}}**: Less than 3A
    
    | PART NUMBER | MANUFACTURER | TYPE | $C_{\text{iss}}$ (pF) | $C_{\text{rss}}$ (pF) | $C_{\text{rss}} / (C_{\text{iss}} + C_{\text{rss}})$ |
    |-------------|------------|------|-------------------|------------------|------------------------|
    | uPA2751GR   | NEC        | Dual | 1040              | 130              | 0.111                  |
    | IRF7313     | International Rectifier | Dual | 650              | 130              | 0.167                  |
  - **I_{\text{OUT}}**: More than 3A
    
    | PART NUMBER | MANUFACTURER | TYPE | $C_{\text{iss}}$ (pF) | $C_{\text{rss}}$ (pF) | $C_{\text{rss}} / (C_{\text{iss}} + C_{\text{rss}})$ |
    |-------------|------------|------|-------------------|------------------|------------------------|
    | SUD30N03    | Vishay     | Single | 1170           | 30               | 0.049                  |
    | SUD70N03    | Vishay     | Single | 2700           | 360              | 0.118                  |

* It is recommended to use MOSFETs with $C_{\text{iss}}$ less than 3000pF.
* For $T_{\text{r2}}$, MOSFETs with smaller $C_{\text{rss}} / (C_{\text{iss}} + C_{\text{rss}})$ are recommended.

- **Recommended Coil (L)**

*(*1)Please place $C_{\text{IN}}$ close to $R_{\text{SENSE}}$ as much as possible, so that an impedance does not occur between the elements.  
A 1$\mu$F ceramic capacitor is recommended for CVL.

*(*2)Operation may become unstable if a ceramic capacitor is used for $C_{\text{L}}$.  
A 100$\mu$F ceramic capacitor is recommended for $C_{\text{L}}$. 
A 150$\mu$F ceramic capacitor is recommended for $C_{\text{L}}$.  
A 22$\mu$F ceramic capacitor is recommended for CVL.

For stable operation, please use a coil with $L$ less than 22 $\mu$H.
**EXTERNAL COMPONENTS (Continued)**

- **Output Voltage Setting (RFB1, RFB2, CFB)**
  Output voltage can be set by adding external split resistors. Output voltage is determined by the following equation, based on the values of RFB1 and RFB2. The sum of RFB1 and RFB2 should normally be 2 MΩ or less \((RFB1 + RFB2 \leq 2M \Omega)\).
  \[
  V_{OUT} = \frac{RFB1}{RFB2 + 1}
  \]
  The value of CFB, speed-up capacitor for phase compensation, should be adjusted by the following equation.
  \[
  f_{zFB} = \frac{1}{(2 \pi \times CFB \times RFB1)} \approx 10kHz
  \]
  Adjustments are required from 1kHz to 50kHz depending on the application, value of inductance (L), and value of load capacity (CL).

- **Setting Latch Protection Circuit Delay Time (CPRO)**
  Time delay is 4.7 ms (TYP.) under the current conditions if CPRO has 4,700 pF. This time delay is roughly proportional to the value of CPRO.

  ex.) When CPRO is 2200pF, \(4.7ms\) (TYP.) \times 2200pF / 4700pF = 2.2ms (TYP.)
  When CPRO is 0.01 μF (10,000pF), \(4.7ms\) (TYP.) \times 10000pF / 4700pF = 10ms (TYP.)

  * For stable operation, please use a capacitor with more than 2200pF as CPRO.

- **Setting Soft-Start Time (CSS)**
  Relationships between the value of CSS and the soft-start time (25°C TYP.) are shown at left. For stable operation, please use a capacitor with more than 2200pF as CSS.
**EXTERNAL COMPONENTS (Continued)**

- **Sense Resistance (RSENSE)**

  The below values can be adjusted by using sense resistance (RSENSE).

  It is recommended using the RSENSE value in the range of 20mΩ to 100mΩ.

  1) Detect current value of the overcurrent detect circuit

     Maximum output current (IOUTMAX) can be adjusted as the equation below.

     \[
     I_{OUT\text{MAX}} (A) = \frac{200mV \text{ (MAX.)}}{R_{SENSE} \text{ (m}\Omega)}
     \]

     When 4V ≤ VIN < 5V, the maximum output current becomes larger than the calculated value. Please also refer to the characteristics performance below.

     ![VIN vs. IOUTMAX](image)

     - **Topr:25°C VOUT:1.8V,**
     - **VSENSE:159mV, RSENSE:33mΩ**

  2) Peak current value of the current limit PFM control

     Peak current value of the current limit PFM control (I_PFM) varies depending on the dropout voltage (V_{diff}), the coil (L) value and the sense resistance value (RSENSE). For the XC9213 series' sample with voltage sense (VSENSE) 170mV, the characteristic performance below shows the changes in the peak current (I_PFM) when the sense resistance values (RSENSE) are 20mΩ, 33 mΩ, and 50 mΩ. The peak current varies according to the dropout voltage and the coil value.

     ![PFM Peak Current](image)

     - **RSENSE:20mΩ**
     - **RSENSE:33mΩ**
     - **RSENSE:50mΩ**

     The sense voltage varies within the range of 145 mV ≤ VSENSE ≤ 200mV. The peak current as shown in three graphs fluctuates according to the sample's sense voltage.
**EXTERNAL COMPONENTS (Continued)**

- Divided Resistors For VD Input Voltages (RVDIN1, RVDIN2)
  Detect voltage of the detector block can be adjusted by the external divided resistors for VD input voltages (RVDIN1, RVDIN2) as the equation below.
  When $0.855V \leq VDF \leq 0.925V$ (0.9V TYP.)
  \[\text{Detect voltage} = VDF \times \frac{RVDIN1 + RVDIN2}{RVDIN2} \text{[V]}\]
  Please select RVDIN1 and RVDIN2 as the sum of RVDIN1 and RVDIN2 becomes less than 2MΩ.

- Divided Resistor For VD Output Voltage (RVDOUT)
  Output type of the detector block is N-channel open drain. Please use a 1kΩ resistor or more as RVDOUT.

**NOTES ON USE**

1. For temporary, transitional voltage drop or voltage rising phenomenon, the IC is liable to malfunction should the ratings be exceeded.

2. This IC should be used within the stated absolute maximum ratings in order to prevent damage to the device.

3. Overcurrent Limit Function
   The internal current detection circuit is designed to monitor voltage occurs between RSENSE resistors in the overcurrent condition. In case that the overcurrent limit function operates when the output is shorted, etc., the current detection circuit detects that the voltage between RSENSE resistors reaches the SENSE voltage (170mV TYP.), and, thereby, the overcurrent limit circuit outputs the signal, which makes High side’s N-ch MOSFET turn off. Therefore, delay time will occur (300ns TYP.) after the current detection circuit detects the SENSE voltage before High side’s N-ch MOSFET turns off. When the overcurrent limit function operates because of rapid load fluctuation etc., the SENSE voltage will spread during the delay time without being limited at the voltage value, which is supposed to be limited. Therefore, please be noted to the absolute maximum ratings of external MOSFET, a coil, and an Schottky diode.

4. Short Protection Circuit
   In case that a power supply is applied to the IC while the output is shorted, or the IC is switched to enable state from disable state via the CE pin, when High side’s N-ch MOSFET is ON and Low side’s N-ch MOSFET is OFF, the potential difference for input voltage will occur to the both ends of a coil. Therefore, the time rate of coil current becomes large. By contrast, when High side’s N-ch MOSFET is OFF and Low side’s N-ch MOSFET is ON, there is almost no potential difference at both ends of the coil since the output voltage is shorted to the Ground. For this, the time rate of coil current becomes quite small. This operation is repeated within soft-start time; therefore, coil current will increase for every clock. Also with the delay time of the circuit, coil current will be converged on a certain current value without being limited at the current amount, which is supposed to be limited. However, step-down operation will stop and the circuit can be latched if FB voltage is decreasing to the voltage level, which enables to operate a short protection circuit when the soft-start time completes. Even if the FB voltage is not decreasing to the voltage level, which a short protection circuit cannot be operated, the step-down operation stops when CPRO time completes, and the circuit will be latched.
   Please be noted to the absolute maximum ratings of external MOSFET, a coil, and an Schottky diode.
5. Current Limit PFM Control

With a built-in bootstrap buffer driver circuit, the XC9213 series generates voltage for Tr1 to be turned on by charging CBST with VL (4V). When Tr1 is off, Tr2 is on, and the Lx signal is low, it will be suitable timing for charging CBST. (Please refer to the above figure.) For that reason, at PFM control (MODE: Low), the clock pulses will decrease extremely according to the decrease of the load current. As a result, it will cause a decrease of charging frequency and an electric discharge of CBST so that sufficient voltage for the Tr1 to be turned on will not be supplied. Therefore,

1) Please use a Schottky Barrier Diode with few reverse current values for SD2.
2) Please avoid extreme light loads (e.g. less than a few mA)

Moreover, the above-mentioned operation may occur, influenced by external components including SD2 and ambient temperature. It’s recommended to use the IC after evaluation with an actual device.

6. Torex places an importance on improving our products and their reliability.

We request that users incorporate fail-safe designs and post-aging protection treatment when using Torex products in their systems.
