18V Driver Transistor Built-In Synchronous Step-Down DC/DC Converter

**GENERAL DESCRIPTION**
The XC9248 series is 18V bootstrap synchronous step-down DC/DC converter with built-in Nch-Nch driver transistors. With an input voltage range from 4.5V to 18V and a maximum output current of 2.2A, the series is suitable for digital home appliance power supplies and can be used with small ceramic capacitors.
The series has a 0.8V reference voltage, and using externally connected resistors, the output voltage can be set freely from 1.0V to 12V.
The control method is synchronous PWM (Source/ Sink). The soft start time is internally set to 2.8ms (TYP.), also can be adjusted using external capacitor.
With UVLO (Under Voltage Lock Out) function, the internal driver transistors are forced OFF when input voltage falls down below 3.8V (TYP.).
The series includes over current protection, \( V_{OUT} \) short-circuit protection, \( L_x \) short-circuit protection, \( V_{OUT} \) overvoltage protection and thermal shutdown.

**APPLICATIONS**
- Digital home appliance
- Office automation equipment
- Note PCs / Tablet PCs
- Car accessories power supplies

**FEATURES**
- Input Voltage: 4.5V ~ 18V
- Output Voltage: 1.0V ~ 12V (\( V_F=0.8V\pm1.5\% \)) (*1)
- Output Current: 2.2A
- Efficiency: 93.8% (*1) \( @V_R=12V, V_{OUT}=5V, I_{OUT}=700mA \)
- Oscillation Frequency: 500kHz
- Maximum Duty Cycle: 79%
- Soft-Start Time: Fixed 2.8ms, set by external capacitor
- Protection Circuit:
  - UVLO
  - High side over current protection
  - Low side over current protection
  - \( V_{OUT} \) Short-circuit Protection
  - \( L_x \) Short-circuit Protection
  - \( V_{OUT} \) Over voltage protection
  - Thermal shutdown
- Package: SOP-8FD
- Environmentally Friendly: EU RoHS Compliant, Pb Free

(*1) Performance depends on external components and wiring on the PCB.

**TYPICAL APPLICATION CIRCUIT**

(*) The over-current protection latch is an integral latch type.

(**) To prevent an extremely large rush current from flowing in the event that Lx is short-circuited, both the A & B types have an Lx short protection latch function.
■ PIN CONFIGURATION

![SOP-8FD (TOP VIEW)](image)

* The dissipation pad for the SOP-8FD package should be solder-plated in recommended mount pattern and metal masking so as to enhance mounting strength and heat release. If the pad needs to be connected to other pins, it should be connected to the GND (No.7) pin.

### <Coil current setting>

For stable operation by current feedback control, the XC9248 series is optimum when the peak-to-peak current (I<sub>pk</sub>) in the coil is set approximately between 0.5A to 1A. The I<sub>pk</sub> value can be calculated by using the following equation:

\[
I_{pk}[A] = \frac{(V_{IN} - V_{OUT}) \times V_{OUT}}{V_{IN}} / 0.5 / L[\mu H]
\]

L : Coil Inductance

TOREX

7/22
<VOUT setting>
The output voltage can be set by connecting external dividing resistors. The output voltage is determined by the values of RFB1 and RFB2 as given in the equation below. The total of RFB1 and RFB2 should be less than 150kΩ. Output voltage range can be set freely from 1.0V to 12V with a 0.8V reference voltage.

\[ V_{OUT} = 0.8 \times \frac{R_{FB1} + R_{FB2}}{R_{FB2}} \]

Adjust the value of the phase compensation speed-up capacitor CFB so that \( f_{zfb} = \frac{1}{2 \times \pi \times C_{FB} \times R_{FB1}} \) is about 7kHz. Adjustments are required from 5kHz to 50kHz depending on the application, value of inductance (L), and value of load capacitance (CL).

**Examples**

\[ R_{FB1} = 47kΩ, \quad R_{FB2} = 15kΩ, \quad V_{OUT} = 0.8V \times \frac{47kΩ + 15kΩ}{15kΩ} = 3.3V \]

\[ C_{FB} = 470pF, \quad f_{zfb} = \frac{1}{2 \times \pi \times 470pF \times 47kΩ} = 7.2kHz \]

<Minimum VOUT>
The Minimum VOUT is set by MINDUTY. The MINDUTY changes by the external inductance (L).
For the L value, please choose the optimal value – see P.7 <Coil current setting>. The Minimum VOUT can be calculated by using the following equation:

\[ V_{OUT} = V_{IN} \times \text{MINDUTY} / 100 \]

**L vs. MINDUTY**

<External soft-start setting>
A capacitor can be connected to the SS pin to set a time longer than the internal soft-start time voluntarily. By setting the EN pin to the VENH voltage or higher, a current \( I_{SS} = 4μA \) (TYP.) flows to the SS pin and charges the capacitor. When the SS pin voltage attains the SS threshold voltage \( V_{SSTH} = 1.8V \) (TYP.), the output voltage reaches about 90% of the set voltage. External soft-start can be calculated by using the following equation:

\[ \text{External soft-start time} = V_{SSTH} \times C_{SS} / I_{SS} \]

**Examples**

\[ C_{SS} = 0.1μF, \quad \text{External soft-start time} = 1.8V \times 0.1μF / 4μA \times 1000 = 45ms \]
OPERATIONAL EXPLANATION

The XC9248 series consists of a reference voltage source, an internal reference voltage source, ramp wave circuit, error amplifier, PWM comparator, phase compensation circuit, Nch MOS driver transistor, current limiter circuit, UVLO, short protection circuit, thermal shutdown circuit, over voltage protection and others. (See the block diagram below.)

By using the error amplifier, the FB pin voltage is compared with the internal reference voltage. The signal is input into the PWM comparator to determine the on time of switching. The signal from the error amplifier is compared with the ramp wave from the ramp wave circuit, and the resulting output is delivered to the output buffer circuit to provide on-time of the duty cycle at the LX pin. This process is continuously performed to ensure stable output voltage.

The current feedback circuit monitors the Nch MOS driver transistor current for each switching operation, and modulates the error amplifier output signal to provide multiple feedback signals. This enables a stable feedback loop even when using a low ESR capacitor such as ceramic, which results in ensuring stable output voltage.

<Reference Voltage Source>
The reference voltage source provides the reference voltage to ensure stable output voltage of the DC/DC converter.

<Ramp Wave Circuit>
The ramp wave circuit determines switching frequency. The frequency is fixed 500kHz internally. Clock pulses generated in this circuit are used to produce ramp waveforms needed for PWM operation, and to synchronize all the internal circuits.

<Error Amplifier>
The error amplifier is designed to monitor output voltage. The amplifier compares the reference voltage with the feedback voltage. When a voltage lower than the reference voltage is fed back, the output voltage of the error amplifier increases. The gain and frequency characteristics of the error amplifier output are fixed internally to deliver an optimized signal to the mixer. The error amplifier output signal optimized in the mixer is modulated with the current feedback signal. This signal is delivered to the PWM comparator.
<Current limiting>
The current limiting circuit of the XC9248 series monitors the current that flows through the Low side and High side Nch MOS driver Tr, and when over-current is detected, the current limiting function activates.

1. Low side driver current limiting
   The current in the Low side driver Tr. is detected to equivalently monitor the bottom value of the coil current. The Low side driver current limiting function prohibits the High side driver Tr. from turning on in an over-current state where the bottom value of the coil current is higher than the Low side driver current limit value \( I_{LIMLS} \). Control to lower the switching frequency \( f_{OSC} \) is also performed. When the over-current state is released, normal operation resumes.

2. High side driver current limiting + Low side driver current limiting
   The current in the High side driver Tr. is detected to equivalently monitor the peak value of the coil current. The High side driver current limiting function forcibly turns off the High side driver Tr. when the peak value of the coil current reaches the High side driver current limit value \( I_{LIMHS} \). \( I_{LIMLS} < I_{LIMHS} \) is set inside the IC, and therefore the Low side driver current limiting function of 1 above also detects the over-current state at this time. When the over-current state is released, normal operation resumes.

3. Over-current latch (Type A)
   Type A turns off the High side and Low side driver transistors when state 1 or 2 continues for 1.1 ms (TYP.). The \( L_X \) pin is in the \( C_L \) discharged state, and is latch-stopped at the GND level (0V).
   The latch-stopped state only stops the pulse output from the \( L_X \) pin; the internal circuitry of the IC continues to operate.
   To restart after latch-stopping, L level and then H level must be input into the EN pin, or \( V_{IN} \) pin re-input must be performed (after lowering the voltage below the UVLO detection voltage) to resume operation by soft start.
   The over-current latch function may occasionally be released from the current limit detection state by the effects of ambient noise, and it may also happen that the latch time becomes longer or latching does not take place due to board conditions. For this reason, place the input capacitor as close as possible to the IC.

Type B is an automatic recovery type that performs the operation of 1 or 2 until the over-current state is released.

Low side driver current limit value \( I_{LIMLS} = 2.1A \) (MIN.)
High side driver current limit value \( I_{LIMHS} = 4.1A \) (TYP.)
<Thermal Shutdown>
For protection against heat damage of the ICs, thermal shutdown function monitors chip temperature. The thermal shutdown circuit starts operating and the Nch MOS driver transistor will be turned off when the chip’s temperature reaches 150°C. The LX pin enters the C↓ discharged state and stops functioning at GND level (0V). When the temperature drops to 125°C or less after shutting of the current flow, the IC performs the soft-start function to initiate output startup operation.

<UVLO Circuit>
When the VIN voltage becomes 3.8V (TYP.) or lower, the Nch MOS driver transistor is forced OFF. The LX pin enters the C↓ discharged state and stops functioning at GND level (0V). When the VIN voltage becomes 3.9V (TYP.) or higher, switching operation takes place. By releasing the UVLO function, the IC performs the soft-start function to initiate output startup operation. The soft-start function operates even when the VIN voltage falls momentarily below the UVLO detect voltage. The UVLO circuit does not cause a complete shutdown of the IC, but causes pulse output to be suspended; therefore, the internal circuitry remains in operation.

<Bootstrap method>
An Nch MOS driver Tr. is used for the High side driver, and a voltage higher than the VIN voltage is needed to turn the driver on. For that purpose, the bootstrap method is used to generate a voltage higher than the VIN voltage. The CBST capacitance is connected between BST and LX, and because the V↓L voltage is lower than the 4.6V (TYP.) VL voltage that is the internal power supply, CBST is charged from VL.

<VOUT short-circuit protection>
With the A type, when the output voltage VOUT is shorted to GND or is near a shorted state (the FB voltage is 1/2 or lower), and a current over the current limit flows to the High side or Low side driver Tr., a VOUT short circuit is detected and the High side and Low side driver Trs. are immediately turned off and latched. The LX pin enters the C↓ discharged state and stops functioning at GND level (0V). Once in the latched state, operation is resumed by either turning the IC off and restarting with the EN pin, or by re-input into the VIN pin (the voltage is lowered below the under-voltage lockout detection voltage once).

<LX short-circuit protection>
If the event that the LX pin shorts to GND, LX short-circuit protection activates for protection from over-current due to rush current and to protect the IC.
If the LX pin shorts to GND, High side current limiting will activate due to rush current when the High side driver Tr. turns on. The High side driver Tr. turns off, and the Low side driver Tr. turns on at the same time. At this time, if Low side current limiting did not activate, an LX short-circuit is detected, and the Low side driver is turned off and latched at the same time as the High side driver Tr. Once in the latched state, operation is resumed by either turning the IC off and restarting with the EN pin, or by re-input into the VIN pin (the voltage is lowered below the under-voltage lockout detection voltage once).

<VOUT over-voltage protection>
To minimize output voltage overshoot, VOUT over-voltage protection activates when VOUT overshoot occurs due to the output resistance changing from a heavy load to a light load or otherwise. When VOUT overshoot occurs and the FB voltage that senses VOUT rises to 0.9V (TYP.) or more, the High side driver Tr. is immediately turned off and the Low side driver Tr. is turned on to prevent VOUT overshoot. When the FB voltage falls to 0.8V (TYP.) or less due to hysteresis, the High side driver Tr. turns on at the next clock cycle.
OPERATIONAL EXPLANATION (Continued)

"<C<sub>L</sub> high-speed discharge function>
When L level is input into the EN pin and the IC enters the standby state, the charge on the output capacitor C<sub>L</sub> can be discharged at high speed with the Nch MOS switch Tr. incorporated between L<sub>x</sub> and GND. This enables the prevention of application malfunctioning due to C<sub>L</sub> charge remaining when the IC stops.
The C<sub>L</sub> discharge time can be calculated from the equation below. Note that the equation varies depending on the set voltage V<sub>OUT(E)</sub>.

(1) Equation when the set voltage V<sub>OUT(E)</sub> is 1V to 4V.
The C<sub>L</sub> discharge time is determined by C<sub>L</sub> and R<sub>DCHG</sub>. If the time constant of C<sub>L</sub> and R<sub>DCHG</sub> is τ (τ = C<sub>L</sub>×R<sub>DCHG</sub>), the output voltage discharge time can be calculated by using the following equation:

\[ t = \tau \ln \left( \frac{V_{OUT(E)}}{V} \right) \]

V : Output voltage after discharge
V<sub>OUT(E)</sub> : Output voltage
τ : Discharge time
C<sub>L</sub>×R<sub>DCHG</sub>

(2) Equation when the set voltage V<sub>OUT(E)</sub> is 4.1V to 12V.
The C<sub>L</sub> discharge time is determined by constant current until V<sub>OUT(E)</sub> is 4 V. When 4V or less, it is determined by C<sub>L</sub> and R<sub>DCHG</sub> as in (1). If τ = C<sub>L</sub>×R<sub>DCHG</sub> is the time constant of C<sub>L</sub> and R<sub>DCHG</sub> and the C<sub>L</sub> discharge current is I<sub>DCHG</sub>, the discharge time of the output voltage can be calculated by using the following equation:

\[ t = \tau \ln \left( \frac{4}{V} \right) + \frac{C_L}{I_{DCHG}} (V_{OUT(E)} - 4) \]

V : Output voltage after discharge
V<sub>OUT(E)</sub> : Output voltage,
t: Discharge time
τ : C<sub>L</sub>×R<sub>DCHG</sub>
I<sub>DCHG</sub> : CL : Discharge time
NOTE ON USE

1. For temporary, transitional voltage drop or voltage rising phenomenon, the IC is liable to malfunction should the ratings be exceeded.

2. The DC/DC converter characteristics depend greatly on the externally connected components as well as on the characteristics of this IC, so refer to the specifications and typical standard circuit examples of each component when carefully considering which components to select. Be especially careful of the capacitor characteristics and use B characteristics (JIS standard) or X7R, X5R (EIA standard) ceramic capacitors.

3. Where wiring impedance is high, operations may become unstable due to noise and/or phase lag depending on output current. Please wire the input capacitor \( C_{IN} \) and the output capacitor \( C_{L} \) as close to the IC as possible.

4. This IC monitors Peak to Peak current in the coil by means of a Low side driver current limiting circuit and a High side driver current limiting circuit. The Peak to Peak current varies depending on the difference between the input voltage and the output voltage as well as the L value of the coil and thus, in some cases, current limiting may activate too frequently and cause operation to become unstable or the current may not reach the maximum output current.

5. With the A type, when a sharp load fluctuation occurs, the \( V_{OUT} \) voltage drop is conveyed directly to the FB pin through \( C_{FB} \), and short-circuit protection may activate at a voltage higher than 1/2 the \( V_{OUT} \) voltage.

6. The \( V_L \) pin is the output of the internal regulator for operation of the DC/DC control block. For stable operation, always connect an external capacitor \( C_{VL} \) to the \( V_L \) pin. Do not use the \( V_L \) pin for external power supply, as it has been optimized as a local power supply.

7. With this IC, operation may become unstable at the minimum operating voltage or less.

8. Make sure that the absolute maximum ratings of the external components and of this IC are not exceeded.

9. Torex places an importance on improving our products and their reliability. We request that users incorporate fail-safe designs and post-aging protection treatment when using Torex products in their systems.
NOTES ON USE (Continued)

10. Instructions for pattern layouts

(1) In order to stabilize V_IN voltage level, we recommend that a by-pass capacitor (CIN) be connected as close as possible to the V_IN and GND pins.

(2) Please mount each external component as close to the IC as possible.

(3) Wire external components as close to the IC as possible and use thick, short connecting traces to reduce the circuit impedance.

(4) Make sure that the GND traces are as thick as possible, as variations in ground potential caused by high ground currents at the time of switching may result in instability of the IC.

(5) Internal driver transistors bring on heat because of the output current (IOUT) and ON resistance of the Nch MOS driver transistors.

### SOP-8FD Power Dissipation

Power dissipation data for the SOP-8FD is shown in this page. The value of power dissipation varies with the mount board conditions. Please use this data as the reference data taken in the following condition.

#### 1. Measurement Condition

- **Condition:** Mount on a board
- **Ambient:** Natural convection
- **Soldering:** Lead (Pb) free
- **Board:** Dimensions 40 x 40 mm (1600 mm² in one side)
  - Copper (Cu) traces occupy 50% of the board area in top and back faces
  - Package heat-sink is tied to the copper traces
- **Material:** Glass Epoxy (FR-4)
- **Thickness:** 1.6mm
- **Through-hole:** 4 x 0.8 Diameter

#### 2. Power Dissipation vs. Ambient Temperature

1. The product and product specifications contained herein are subject to change without notice to improve performance characteristics. Consult us, or our representatives before use, to confirm that the information in this datasheet is up to date.

2. The information in this datasheet is intended to illustrate the operation and characteristics of our products. We neither make warranties or representations with respect to the accuracy or completeness of the information contained in this datasheet nor grant any license to any intellectual property rights of ours or any third party concerning with the information in this datasheet.

3. Applicable export control laws and regulations should be complied and the procedures required by such laws and regulations should also be followed, when the product or any information contained in this datasheet is exported.

4. The product is neither intended nor warranted for use in equipment of systems which require extremely high levels of quality and/or reliability and/or a malfunction or failure which may cause loss of human life, bodily injury, serious property damage including but not limited to devices or equipment used in 1) nuclear facilities, 2) aerospace industry, 3) medical facilities, 4) automobile industry and other transportation industry and 5) safety devices and safety equipment to control combustions and explosions. Do not use the product for the above use unless agreed by us in writing in advance.

5. Although we make continuous efforts to improve the quality and reliability of our products; nevertheless Semiconductors are likely to fail with a certain probability. So in order to prevent personal injury and/or property damage resulting from such failure, customers are required to incorporate adequate safety measures in their designs, such as system fail safes, redundancy and fire prevention features.

6. Our products are not designed to be Radiation-resistant.

7. Please use the product listed in this datasheet within the specified ranges.

8. We assume no responsibility for damage or loss due to abnormal use.

9. All rights reserved. No part of this datasheet may be copied or reproduced unless agreed by Torex Semiconductor Ltd in writing in advance.
